Assignment 4

Jacob O

2023-10-31

Question 1

- 1. A common task is to take a set of data that has multiple categorical variables and create a table of the number of cases for each combination. An introductory statistics textbook contains a dataset summarizing student surveys from several sections of an intro class. The two variables of interest for us are Gender and Year which are the students gender and year in college.
 - a) Download the dataset and correctly order the Year variable using the following:

```
Survey <- read.csv('http://www.lock5stat.com/datasets3e/StudentSurvey.csv', na.strings=c('',''
```

b) Using some combination of `dplyr` functions, produce a data set with eight rows that contains the number of responses for each gender:year combination. Make sure your table orders the `Year` variable in the correct order of `First Year`, `Sophmore`, `Junior`, and then `Senior`. *You might want to look at the following functions: `dplyr::count` and* *`dplyr::drop_na`.*

```
John.Frankfurt <- Survey %>%
  drop_na(Year, Sex) %>%
  dplyr::count(Year, Sex) %>%
  arrange(Year!='Sophomore') %>%
  arrange(Year!='FirstYear')
John.Frankfurt
```

```
##
          Year Sex n
## 1 FirstYear
                 F 43
## 2 FirstYear
                 M 51
## 3 Sophomore
                F 96
## 4 Sophomore
                 M 99
## 5
        Junior
                 F 18
## 6
        Junior
                 M 17
## 7
                 F 10
       Senior
## 8
       Senior
```

c) Using `tidyr` commands, produce a table of the number of responses in the following form:

```
tabulaaaarrrr <- table(Survey$Sex, Survey$Year)
tabulaaaarrrr
```

##

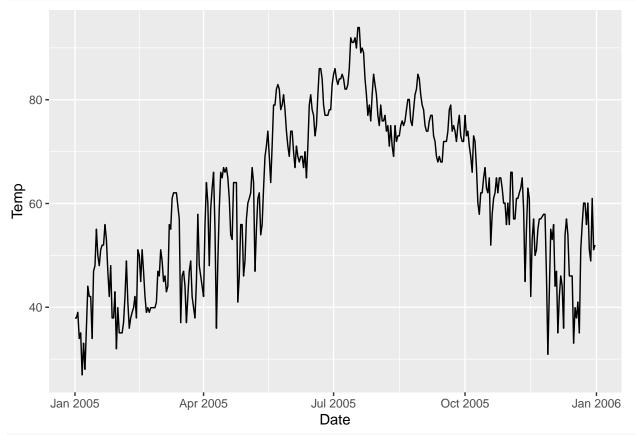

```
## FirstYear Junior Senior Sophomore
## F 43 18 10 96
## M 51 17 26 99
```

Question 2

- 2. From the book website, there is a .csv file of the daily maximum temperature in Flagstaff at the Pulliam Airport. The direction link is at: https://raw.githubusercontent.com/dereksonderegger/444/master/da ta-raw/FlagMaxTemp.csv
 - a) Create a line graph that gives the daily maximum temperature for 2005. Make sure the x-axis is a date and covers the whole year.

```
filedata <- read.csv('https://raw.githubusercontent.com/dereksonderegger/444/master/data-raw/FlagMaxTem/hehehe.yup <- filedata %>%
    filter(Year==2005) %>%
    pivot_longer(X1:X31, names_to = 'Day', values_to = 'Temp') %>%
    mutate(Day = str_sub(Day, start=2, end=-1)) %>%
    mutate(Date = make_date(year=Year, month=Month, day=Day)) %>%
    drop_na()

ggplot(hehehe.yup, aes(x=Date, y=Temp)) +
    geom_line()
```

```
head(hehehe.yup)
```

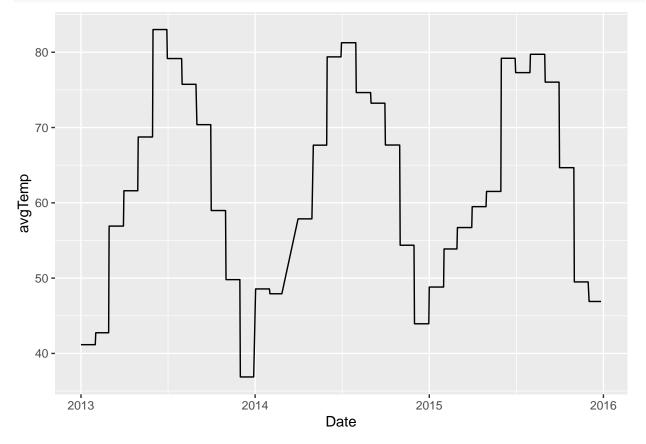

```
## # A tibble: 6 x 6
## X Year Month Day Temp Date
## <int> <int> <int> <chr> <dbl> <date>
```

```
235
            2005
                               37.9 2005-01-01
## 1
                      1 1
## 2
       235
            2005
                      1 2
                               37.9 2005-01-02
## 3
            2005
                      1 3
       235
                               39.0 2005-01-03
## 4
       235
            2005
                      1 4
                               34.0 2005-01-04
## 5
       235
            2005
                      1 5
                               35.1 2005-01-05
## 6
       235
            2005
                      1 6
                               27.0 2005-01-06
```

b) Create a line graph that gives the monthly average maximum temperature for 2013 - 2015. *Again the x-axis should be the date and the axis* *spans 3 years.*

```
hehehe.yup <- filedata %>%
  filter(Year >= 2013 & Year <= 2015) %>%
  pivot_longer(X1:X31, names_to = 'Day', values_to = 'Temp') %>%
  mutate(Day = str_sub(Day, start=2, end=-1)) %>%
  mutate(Date = make_date(year=Year, month=Month, day=Day)) %>%
  drop_na() %>%
  group_by(Month, Year) %>%
  mutate(avgTemp = mean(Temp))

ggplot(hehehe.yup, aes(x=Date, y=avgTemp)) +
  geom_line()
```

Question 4

4. For this problem we will consider two simple data sets.

```
A <- tribble(
  ~Name, ~Car,
  'Alice', 'Ford F150',
  'Bob', 'Tesla Model III',
  'Charlie', 'VW Bug')
B <- tribble(
 ~First.Name, ~Pet,
  'Bob', 'Cat',
  'Charlie', 'Dog',
 'Alice', 'Rabbit')
```

a) Squish the data frames together to generate a data set with three rows and three columns. Do two

```
ways: first using cbind and then using one of the dplyr join commands.
bounded.baybeeee <- cbind(A, B$Pet)</pre>
head(bounded.baybeeee)
##
        Name
                         Car B$Pet
## 1
       Alice
                   Ford F150
                                 Cat
## 2
         Bob Tesla Model III
                                 Dog
## 3 Charlie
                      VW Bug Rabbit
join.us <- full_join(A,B, by = join_by(Name == First.Name))</pre>
head(join.us)
## # A tibble: 3 x 3
##
     Name
                             Pet
             Car
##
     <chr>
             <chr>
                             <chr>
## 1 Alice Ford F150
                             Rabbit
## 2 Bob
             Tesla Model III Cat
## 3 Charlie VW Bug
                             Dog
b) It turns out that Alice also has a pet guinea pig. Add another row to
    the `B` data set. Do this using either the base function `rbind`, or
    either of the `dplyr` functions `add_row` or `bind_rows`.
B <- rbind(B, c("Alice", "Guinea Pig"))</pre>
## # A tibble: 4 x 2
##
   First.Name Pet
##
     <chr>
                <chr>
                Cat
## 1 Bob
## 2 Charlie
                Dog
## 3 Alice
                Rabbit
## 4 Alice
                Guinea Pig
c) Squish the `A` and `B` data sets together to generate a data set with
    four rows and three columns. Do this two ways: first using `cbind` and
    then using one of the `dplyr` `join` commands. Which was easier to
    program? Which is more likely to have an error.
```

join.us <- full_join(A,B, by = join_by(Name == First.Name))</pre>

join.us

```
## # A tibble: 4 x 3
##
                               Pet.
     Name
             Car
     <chr>>
             <chr>>
##
                               <chr>>
## 1 Alice
            Ford F150
                               Rabbit
## 2 Alice
             Ford F150
                               Guinea Pig
## 3 Bob
             Tesla Model III Cat
## 4 Charlie VW Bug
#bounded.baybeeee <- cbind(A, B$Pet)</pre>
#bounded.baybeeee
```

The cbind operation errored out because of a size mismatch, whereas the full join one just recycled a row from one of the inputs to complete the table. cbind will force you to be more accurate while join will be more flexible.

Question 5

5. Data table joins are extremely common because effective database design almost always involves having multiple tables for different types of objects. To illustrate both the table joins and the usefulness of multiple tables we will develop a set of data frames that will represent a credit card company's customer data base. We will have tables for Customers, Retailers, Cards, and Transactions. Below is code that will create and populate these tables.

```
Customers <- tribble(</pre>
  ~PersonID, ~Name, ~Street, ~City, ~State,
 1, 'Derek Sonderegger', '231 River Run', 'Flagstaff', 'AZ',
 2, 'Aubrey Sonderegger', '231 River Run', 'Flagstaff', 'AZ',
 3, 'Robert Buscaglia', '754 Forest Heights', 'Flagstaff', 'AZ',
  4, 'Roy St Laurent', '845 Elk View', 'Flagstaff', 'AZ')
Retailers <- tribble(</pre>
  ~RetailID, ~Name, ~Street, ~City, ~State,
 1, 'Kickstand Kafe', '719 N Humphreys St', 'Flagstaff', 'AZ',
 2, 'MartAnnes', '112 E Route 66', 'Flagstaff', 'AZ',
 3, 'REI', '323 S Windsor Ln', 'Flagstaff', 'AZ')
Cards <- tribble(</pre>
  ~CardID, ~PersonID, ~Issue_DateTime, ~Exp_DateTime,
  '9876768717278723', 1, '2019-9-20 0:00:00', '2022-9-20 0:00:00',
  '5628927579821287', 2, '2019-9-20 0:00:00', '2022-9-20 0:00:00',
  '7295825498122734', 3, '2019-9-28 0:00:00', '2022-9-28 0:00:00'
  '8723768965231926', 4, '2019-9-30 0:00:00', '2022-9-30 0:00:00')
Transactions <- tribble(</pre>
  ~CardID, ~RetailID, ~DateTime, ~Amount,
  '9876768717278723', 1, '2019-10-1 8:31:23',
                                                  5.68,
  '7295825498122734', 2, '2019-10-1 12:45:45',
                                                25.67,
  '9876768717278723', 1, '2019-10-2 8:26:31',
  '9876768717278723', 1, '2019-10-2 8:30:09',
                                                  9.23.
  '5628927579821287', 3, '2019-10-5 18:58:57', 68.54,
  '7295825498122734', 2, '2019-10-5 12:39:26', 31.84,
  '8723768965231926', 2, '2019-10-10 19:02:20', 42.83)
Cards <- Cards %>%
 mutate( Issue_DateTime = lubridate::ymd_hms(Issue_DateTime),
```

```
Exp_DateTime = lubridate::ymd_hms(Exp_DateTime) )
Transactions <- Transactions %>%
  mutate( DateTime = lubridate::ymd_hms(DateTime))
```

a) Create a table that gives the credit card statement for Derek. It should give all the transactions, the amounts, and the store name. Write your code as if the only initial information you have is the customer's name. Hint: Do a bunch of table joins, and then filter for the desired customer name. To be efficient, do the filtering first and then do the table joins.

```
name <- "Derek Sonderegger"
Derek.customer <- filter(Customers, Name == name)</pre>
Derek.card <- filter(Cards, PersonID == Derek.customer$PersonID)</pre>
Derek.transactions <- filter(Transactions.</pre>
    CardID == Derek.card$CardID)
Derek.trans.retail <- inner_join(Derek.transactions, Retailers, by = join_by(RetailID))
Derek.statement <- select(Derek.trans.retail, DateTime, Amount, Name)</pre>
Derek.statement
## # A tibble: 3 x 3
##
    DateTime
                        Amount Name
     <dttm>
                         <dbl> <chr>
## 1 2019-10-01 08:31:23 5.68 Kickstand Kafe
## 2 2019-10-02 08:26:31 5.68 Kickstand Kafe
## 3 2019-10-02 08:30:09 9.23 Kickstand Kafe
b) Aubrey has lost her credit card on Oct 15, 2019. Close her credit card at
    4:28:21 PM and issue her a new credit card in the `Cards` table.
    *Hint: Using the Aubrey's name, get necessary CardID and PersonID and save*
    *those as `cardID` and `personID`. Then update the `Cards` table row that*
    *corresponds to the `cardID` so that the expiration date is set to the time*
    *that the card is closed. Then insert a new row with the `personID` for*
    *Aubrey and a new `CardID` number that you make up.*
expDate <- ymd_hms("2019 October 15, 4:28:21 PM")
nexExpDate <- expDate + year(5)</pre>
## Warning: tz(): Don't know how to compute timezone for object of class numeric;
## returning "UTC".
Aubrey.customer <- filter(Customers, Name == 'Aubrey Sonderegger')
Aubrey.id <- Aubrey.customer$PersonID</pre>
Aubrey.cards <- filter(Cards, PersonID == Aubrey.id)
Aubrey.cardID <- Aubrey.cards$CardID</pre>
Cards[Cards$CardID ==Aubrey.cardID, 'Exp_DateTime'] <- expDate</pre>
Cards <- rbind(Cards, c('3141592653589', Aubrey.id, '2019-10-15, 16:28:21', '2022-9-20 0:00:00'))
Cards
## # A tibble: 5 x 4
##
     CardID
                     PersonID Issue DateTime
                                                  Exp_DateTime
     <chr>>
                      <chr> <dttm>
                                                  <dttm>
## 1 9876768717278723 1
                              2019-09-20 00:00:00 2022-09-20 00:00:00
## 5 3141592653589 2
                              2019-10-15 07:00:00 2022-09-20 07:00:00
```

c) Aubrey is using her new card at Kickstand Kafe on Oct 16, 2019 at 2:30:21 PM for coffee with a charge of \$4.98. Generate a new transaction for this action.
Hint: create temporary variables `card`, `retailid`, `datetime`, and
`amount` that contain the information for this transaction and then
write your code to use those. This way in the next question you can just
use the same code but modify the temporary variables. Alternatively, you
could write a function that takes in these four values and manipulates the
tables in the GLOBAL environment using the `<<-` command to assign a result</p>
to a variable defined in the global environment. The reason this is OK is
that in a real situation, these data would be stored in a database and we

```
retail.id <- 1
Amount <- 4.98
datetime <- '2019-10-16 14:30:21'
card.id <- '3141592653589'
Transactions <- rbind(Transactions, c(card.id, retail.id, datetime, Amount))
Transactions</pre>
```

```
## # A tibble: 8 x 4
##
   CardID
                     RetailID DateTime
                                                  Amount
##
     <chr>
                     <chr>
                              <dt.tm>
                                                  <chr>>
## 1 9876768717278723 1
                              2019-10-01 08:31:23 5.68
                              2019-10-01 12:45:45 25.67
## 2 7295825498122734 2
## 3 9876768717278723 1
                              2019-10-02 08:26:31 5.68
## 4 9876768717278723 1
                              2019-10-02 08:30:09 9.23
                              2019-10-05 18:58:57 68.54
## 5 5628927579821287 3
## 6 7295825498122734 2
                              2019-10-05 12:39:26 31.84
## 7 8723768965231926 2
                              2019-10-10 19:02:20 42.83
## 8 3141592653589
                    1
                              2019-10-16 21:30:21 4.98
```

would expect the function to update that database.

d) On Oct 17, 2019, some nefarious person is trying to use her OLD credit card at REI. Make sure your code in part (c) first checks to see if the credit card is active before creating a new transaction. Using the same code, verify that the nefarious transaction at REI is denied.

Hint: your check ought to look something like this:

```
card <- '5628927579821287'
retailid <- 3
datetime <- ymd_hms('2019-10-17 14:30:21')
amount <- 4.98

# If the card is currently valid, this should return exactly 1 row.
Valid_Cards <- Cards %>%
    filter(CardID == card, Issue_DateTime <= datetime, datetime <= Exp_DateTime)

# If the transaction is valid, insert the transaction into the table
if( nrow(Valid_Cards) == 1){
    Transactions <- rbind(Transactions, c(card, retailid, datetime, amount))
}else{
    print('Card Denied')
}</pre>
```

[1] "Card Denied"

e) Generate a table that gives the credit card statement for Aubrey. It should give all the transactions, amounts, and retailer name for both credit cards she had during this period.

I tried but I didn't end up figuring this one out
